Abstract

Aims: The aim of this study was to evaluate the post-operative complications using a standardized classification; modified Clavien’s classification.

Patients and methods: We have included all patients aged at least 50-years-old on the day of surgery between the 1st June 2015 and 31st May 2017 at the urology division of Souro Sanou University Teaching Hospital of Bobo-Dioulasso. Complications reports were performed according to the modified Clavien-Dindo system.

Results: Hundred patients (100) presenting a complication after BPH surgery were included in this study in a total of 312 open prostatectomies performed. The post-operative complication rate was 32%. Seventy percent of the patients had at least one complication. Grade I and Grade II complications according to the modified Clavien’s classification system were the most represented (87%). Two patients (2) died in the immediate postoperative period (Grade V). The presence of urethral catheter before surgery was identified as a risk factor for complication. A statistically significant difference was found in the group ICC > 2 (Charlson Index of Comorbidity) for age parameter in the occurrence of complication.

Conclusions: Open prostatectomy is associated with high morbidity in subjects with urinary catheters prior to surgery. Grade I and Grade II according to the modified Clavien’s classification system were the most reported.

Open prostatectomy, Postoperative, Complications

Introduction

Benign prostate hyperplasia (BPH) is the most common urinary problem of the elderly man due to the discomfort for which it is responsible [1]. Surgical management of BPH occupies an important place in the urological activity. Despite the advent of mini invasive treatment as transurethral resection of prostate (TURP), open prostatectomy, the oldest method of BPH treatment, has remained the treatment of choice of BPH in many developing countries [2,3]. Like any surgical technique, it is not free from complications. Clavien’s classification system is an excellent tool of reporting complications associated with surgical procedures. It was used for the first time in 1992 on a case of cholecystectomy [4]. Modified in 2004, it was recommended in 2012 and is validated in 2017 by many scientific societies of urology for post-operative complications reports [5-7]. The aim of this study was to evaluate the post-operative complications of open prostatectomy in order to describe the associated factors.

Patients and Methods

Our study was retrospective and included all the medical records of the patients in whom open transvesical prostatectomy were performed with complications. Data have been collected from June 1st, 2015 to May 31st, 2017 at the urology division of Souro Sanou
University Teaching Hospital of Bobo-Dioulasso. The In-patients and out-patients register of the service, the operative procedure registers, medical records files were used for the collection of the data. Inclusion criteria were clinical observation, programmed open transvesical prostatectomy, and a minimum six months post-operative follow-up. All surgical procedures were performed by urologist surgeons or by senior resident assisted by the urologist surgeon. Fever has been defined by a temperature of at least 38 °C. A level of hemoglobin < 9 g/dl was selected for bleeding requiring blood transfusion. Transitory hematuria was defined as that which persisted for 48 h and then spontaneously resolved. Creatinine and a blood count were performed postoperatively. All patients received antibiotics.

The studied parameters concerned the age, the average weight of the adenoma, the duration of the intervention, the weight of the enucleated tissue, the pre-existing co-morbidities, the operative indication and the postoperative complications. Complications were classified as immediate, early, or late, depending on whether they occurred during the procedure, in the month following surgery, or later. The Charlson Comorbidity Index (Table 1) was used for the assessment of comorbidity factors. Report of complications was made on the basis of the modified Clavien’s classification system (Table 2). Complication grade distributions based on the different Charlson comorbidity indexes were compared using chi-square test and p value < 0.05 was considered significant statistically.

### Results

Out of 312 prostatectomies carried out during the study period, 100 cases of complications were noted, giving a rate of 32.05%.

The average age of patients was 69, 95 years ± 9.10 [50; 86].

The average weight of the adenoma was 113, 25 g ± 39.52 [40; 186].

The average operating time was 107 mn ± 33.91 [60; 180].

Most patients (78%) had a comorbidity Index of Charlson of at least 2.

The characteristics of patients are resumed in Table 3.

Complicated BPH was the main operative indication (71%). Recurrent urinary retention accounted for 83% of these complications. In Table 4, the different indications for prostatectomy are presented.

**Table 2: Classification of complications on the basis of modified Clavien-Dindo system [5].**

| Grade I: Any deviation from normal postoperative course without the need for pharmacological treatment or surgical, endoscopic or interventional radiology. The accepted therapies are drugs such as antiemetic, antipyretics, analgesics, diuretics, electrolytes and physiotherapy. |
| Grade II: Complication requiring pharmacological treatment with drugs other than those used in Grade I complication (including hematuria requiring blood transfusion) |
| Grade III: Complications requiring surgery, endoscopy or interventional radiology |
| Grade IIIa: Intervention carried out under any form of anesthesia other than general anesthesia (including performing a cystostomy) |
| Grade IIIb: Intervention performed under general anesthesia |
| Grade IV: Life-threatening complications (including central neurological complications) |
| Grade IVa: Dysfunction of a single organ. Including renal failure supported by dialysis |
| Grade IVb: Multiple organ dysfunction with Intensive Care Unit admission |
| Grade V: Death of the patient |
were admitted into the operative theatre for surgery were 20 times more likely to develop a post-operative complication (OR = 20.06).

Seventy percent of patients exhibited at least one complication and the majority of these complications (87%) were classified as Grade 1 or 2 according to the modified Clavien’s classification System (Table 2).

**Discussion**

Out of 312 prostatectomies carried out during the study period, 100 cases of complications were noted during twenty-four months, giving a complication rate of 32.05% or approximatively four complications after BPH surgery per month. BPH surgery is the most surgical procedure performed in our urology division comparatively with endoscopic procedures. This prostatic surgery mainly concerned elderly subjects, with an average age of 70, comparable to data from recent series, confirming that this pathology is that of the elderly. Thus Salako, et al. in their study found an average age of 67 years with a complication rate of 36.4%, slightly higher than ours which was 32% [9]. The classic open prostatectomy performed in our department was performed by transvesical route. Hryntschack described the transvesical open prostatectomy, with the principles and steps that are now followed in most urological centres [10]. It is the same technique performed in all our patients. Of all the modalities for treating symptoms of lower urinary tract (LUTS) due to benign prostatic hyperplasia (BPH), prostatectomy provides the highest symptomatic improvement and the lowest failure rate [11]. If in western counties with advanced technology, it is reserved for BPH of 80 g and more [10], in our context it is the main option of treatment. Surgery of BPH is indicated in presence of symptomatic BPH with obstructive or infectious complications or in case of failure of a well-conducted medical treatment using alpha-blockers, the 5-alpha-reductase inhibitors or phytotherapy. In the present study, complications indicated surgery for 60% of patients and 29% of patients were operated because of the failure of well conducted medical treatment.

In our study the complication rate was 32.05%. It is close to the 28% reported by a recent American prospective study [12]. Rates of 40.1% and 17.3% were reported in African and European series respectively [13,14]. Indeed, prostatectomy as an open surgery is known to have higher morbidity compared to other surgical means of symptomatic BPH. Immediate complications (15%) were mainly represented by per operative bleeding with the need for blood transfusion (complication Grade II). Transfusion rates of 7 to 14% were reported in the literature [15,16]. We have reported a blood transfusion rate of 13% among our patients. During surgery, haemostasis consists in the ligation of bleeding arteries per operatively at 5 o’clock and 7 o’clock as described by some authors [17]. A link between the risk of complication and the volume of the prostate could not be determined in this study (Table 5). Traction of the balloon of urethral catheter into the prostatic fossa and haemostasis secured by ligature of bleeding arteries at the bladder neck help in securing the haemostasis [18]. Fever requiring antipyretic administration came as a head of complications grade I (9%). This value was influenced by antibiotherapy post operatively. Other causes of fever like urosepsis, urinary infections, orchi-epididymitis, wound suppurations were eliminated and taken into consideration in other grading of complications as shown in Table 6. Urinary infections were noted in 21% of cases and E.coli was isolated in 76.19% of cases. Patients older than 75-years-old were most at risk and ascending infection through urinary catheter can explain the post-operative bacteriuria [19]. It requires antibiotherapy in our case (Grade II) other factors like long duration in the hospital, long pre-operative hospital admission for more than two days and the time of exposure to the urinary catheter have been identified as risk factors [20]. Parietal suppuration requires dressing at the bed side of the patient, swab
and postoperative course were uneventful for the two patients.

Conclusions

Open transvesical prostatectomy complications are common in our setting. They are mostly Grade I and II of Clavien classification. Two cases of high-Grade V complication (death) were noted. The appearance or the disappearance of post-operative complications depend on the operator experience and on the comorbidity, factors carried by the patient. The frequency of post-operative death is still high and depends on multiple factors. The immediate cause of death still difficult to established without autopsy.
