Abstract

Background: The prevalence of overweight and obesity had considerably increased in developing countries including Ethiopia. In Ethiopia, there is a large variation in prevalence across different regions. There is also inconsistency in the relationship of socioeconomic status (SES) and overweight/obesity across regions. These inconsistencies could make policymakers difficult to make a decision and designing appropriate intervention strategies. Hence, this systematic review and meta-analysis was aimed to generate a pooled prevalence of overweight/obesity and its association with socioeconomic status in Ethiopia, 2020.

Methods: The articles used in this study identified through the electronic search of reputable databases (Google Scholar, EMBASE, Science Direct, PubMed Cochrane library) and hand search of reference lists of previous prevalence studies. Overall, 27 studies were selected based on specified inclusion and exclusion criteria. Data were extracted using a standardized and pre-tested data extraction checklist. The SPSS software program version 20 was used for pooled prevalence analysis while Review Manager 5.3 was used to estimate the pooled effect size of SES and obesity/overweight. The random effect model was used in the meta-analysis and Mantel-Haenszel model was used to calculate odds ratios and their 95% confidence interval.

Result: The pooled prevalence of overweight/obesity among the study population (children, adolescents, and adults) was 13.04% (CI: 12.64%, 13.43%) in Ethiopia. There is a highly positive significant association between high SES/income and overweight/obesity among study subjects (children, adolescents, and adults) in Ethiopia. Accordingly, study populations from higher SES/income groups were 2.35 times higher (OR = 2.35, 95%CI: 1.89, 2.92) times more likely to be overweight/obese compared to other low SES/income groups.

Conclusion: The result revealed that the pooled prevalence of overweight/obesity among children, adolescents, and adults is considerably high, and high SES/income contributes to the risk of overweight/obesity in different population groups in Ethiopia. Therefore, the government of Ethiopia and other concerned bodies should emphasize the prevention and control of overweight/obesity. Intervention strategies and policies with special emphasis on wealthy households should be designed and implemented.

Overweight, Obesity, Socio-economic status, Ethiopia

Abbreviations

Background

World health organization defined overweight and obesity as an excessive accumulation of fat that may impair health [1]. The center for disease control and prevention stated that nearly 30% of the world population is estimated to be either overweight or obese in 2015, of which two-thirds are living in developing countries [2]. About 38.3 million under-five-children was obese [3]. About 2.01 billion adults are overweight.
in 2016 of which 678 million are obese worldwide. Data also implies that the prevalence of overweight and obesity among adults (> 18 years) showed significant increment such that it was raised from 35.7-38.9% and 11.2-13.1%, respectively, from 2010 to 2016 [4]. According to the FAO, IFAD, UNICEF, WFP, and WHO 2019 overweight and obesity continue to increase in all regions. Accordingly, in 2018, nearly 40 million children under five were overweight. In 2016, 131 million children 5-9 years-old, 207 million adolescents, and 2 billion adults were overweight. About a third of overweight adolescents and adults, and 44 percent of overweight children aged 5-9 were obese [5].

The prevalence of overweight/obesity has increased in many developing and low-income countries including Ethiopia. As per available literature from local studies in Ethiopia, the magnitude of overweight/obesity is considerably high and rising in all age groups. According to EDHS 2016, the proportion of women who were overweight or obese has increased from 3% in 2000 to 8% in 2016 [6]. Furthermore, based on the Ethiopian Demographic and Health Survey report, the prevalence of obesity and or overweight increased from 2-2.8%, 6-8%and 2-3% among under-five children, 15-49 years-old women, and 15-49 years-old men, respectively, between 2011 and 2016 [6,7]. The UNICEF 2017 annual report also stated that there is an overall increment of the prevalence of overweight among children from 1.7 to 3.6% in Ethiopia [8].

Overweight and obesity have a negative impact. Overweight and obesity have negative impacts. Pieces of evidence illustrate that obesity is contributing to 4 million deaths globally and is increasing the risk of morbidity for people in all age groups [5]. Overweight or obese population groups are at a higher risk of developing serious health problems such as type 2 diabetes, high blood pressure, asthma, and other respiratory problems, sleep disorders, liver disease, low self-esteem, depression, and social isolation [9]. Obesity has an important contribution to cancer, osteoarthritis, work disability, and sleep apnea and it has a more pronounced impact on morbidity than on mortality [10,11].

In Ethiopia, it has been documented that there is a significant variation in the prevalence of overweight/obesity and its association with socio-economic status (SES) across different regions of the country. Local survey recognized that the prevalence obesity varied from 2.8-13.8% [6,12], 5.1-20.5% [13,14], and 8.3-28.5% [15,16] among children, adolescents and adults in Ethiopia, respectively. On the other hand, there is an inconsistency in the relationship between SES and overweight/obesity across different age groups in the country. Some studies reported that higher SES has no significant association with obesity/overweight [12,17-22]. Other scholars described that there was a negative relationship [13,23], while other studies indicated a positive significant association [24-27].

These disagreements could make policymakers difficult on decision making of designing intervention strategies, implementation, and evaluation. Hence, a better understanding of the prevalence of overweight/obesity across different age groups (children, adolescents, and adults) across different regional groups in particular and country in general will aid decision-making about the best way to implement and evaluate a range of policies and strategies at a national level. On the other hand, understanding the association of socioeconomic status with overweight/obesity also benefits the government and health care provider to provided and focus appropriate nutrition education and counseling for high income or wealthy households. Therefore, this systematic review and meta-analysis was aimed to generate a pooled prevalence of overweight and/or obesity and its association with socioeconomic status in Ethiopia, 2020.

**Methods**

**Study design, study period and literature search approach**

This systematic review and meta-analysis was directed by PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [28]. The literature search was conducted from February to April 2020. All articles until April 30, 2020 were included in this review study. An electronic search of reputable databases (Google Scholar, PubMed, Science Direct, Cochrane library, EMBASE,) was used to identify appropriate articles for this study. Moreover, a hand search of reference lists of previous prevalence studies to find more related and relevant articles was conducted. The keywords used for searching relevant literature were: (i) Population (children, schoolchildren, school-aged, childhood, adolescent, and adults); (ii) Outcome (body composition, overweight, obesity, body weight, weight status, body mass index, anthropometric status (iii) Study design (prevalence, cross-sectional and case-control); and (iv) Specific study area (Ethiopia and regions in Ethiopia). The English language was used to search for articles. Review Manager 5.3 was used to manage references.

**Inclusion criteria**

The articles were included based on the following criteria: (1) Study population: research articles conducted among children, adolescents and adults (2) All prevalence and other cross-sectional studies; and case-control studies; (3) A study conducted and published in the English language were considered. In addition, prevalence studies conducted on children, adolescents and adults were included regardless year of study.
Exclusion criteria

Articles with methodological problems, other than cross-sectional study and did not contain full information and articles that did not contain socio-economic status result were excluded.

Data abstraction and critical appraisal of the studies

Data were extracted by preparing a standardized checklist in Ms-excel sheet version 2013. The extracted data from included articles are the primary author of the article, specific area of the study conducted in Ethiopia, study design, diagnostic information, year of the publication, calculated sample size, response rate, and outcome measures (prevalence of overweight/obesity). The Newcastle-Ottawa quality assessment tool scale was used to appraise the qualities of the studies. The qualities of the studies were assessed by using the following indicators; those with medium (fulfilling 50% of quality assessment criteria) or high quality (≥ 6 out of 10 scales) were considered for inclusion in the meta-analysis.

Identification of eligible studies

The procedures followed for identification and selection of relevant studies is indicated in Figure 1. Totally, 602 articles were searched from electronic data base. Duplicate record (n = 328) were removed from total searched study. One hundred thirty four (n = 134) were excluded by title and (n = 66) were by title and abstract. One hundred forty (n = 140) were excluded since they were not relevant for this meta-analysis in terms of outcome the study is interested. Eighty three (n = 74) full text articles were assessed for eligibility based on the pre-set eligibility criteria of which 47 were excluded as per exclusion criteria. Finally, 27 studies were fulfilled inclusion criteria were included in analysis.

Operationalization of the outcomes of the review

The number of overweight/obese adolescents and adults were the primary outcome of this review and the secondary outcome was socio-economic status defined by wealth index or highest income status. The prevalence of overweight and obesity was calculated by dividing the number of overweight/obese adolescents and/or adults to the total number of adolescents and/or adults included in this study multiplied by 100 (equation 1). The strength and direction of the association between overweight/obesity and socio-economic status were quantified by the odds ratio. The participants were categorized into high either high socio-economic status group or low socio-economic status group for the purpose of analysis. The high socio-economic status category in this systematic review and meta-analysis study is operationally defined as those categorized highest quantiles or wealthiest or highest monthly income group in original study The low socio-economic

---

**Figure 1:** Flow chart diagram describing selection of studies for the systematic review and meta-analysis of magnitude of overweight/obesity and its association with socio-economic status (SES) in Ethiopia, 2020 G.C.
status groups in this study were those medium to low quantiles or having lower monthly income or medium and poor in original study. (Wealthiest/highest income = 1; and the rest wealth/income category = 0).

More than 96% of included studies in meta-analysis were cross-sectional in design and the remaining was case-control. All studies were conducted in different regions of Ethiopia. The minimum and maximum sample sizes included in original studies were 206 and 5465. Twenty five (25) articles from cross-sectional were used for pooled prevalence analysis and twenty seven (27) articles (cross-sectional studies = 25 and case-control studies = 2) were used for meta-analysis to estimate pooled effect size.

**Prevalence of overweight/obesity in Ethiopia**

The pooled and individual prevalence of obesity and/or overweight reported by 25 studies are described in Table 2. Overall, 27,818 subjects (children = 11,488, adolescents = 10,738, adults = 5,594) subjects were included to estimate pooled prevalence of overweight/obesity. Nine hindered ninety six (996) subjects did not include determining prevalence since they are from case-control study. The pooled prevalence of overweight/obesity was 13.04% (CI: 12.64%, 13.43%). The subgroups or separate population group analysis revealed that the pooled prevalence of overweight/obesity among children, adolescents and adults was 12.59% (CI: 11.98%, 13.19%), 11.39% (CI: 10.79%, 11.99%) and 17.13% (CI: 16.14%, 18.11%) respectively.

**Association of socioeconomic status with overweight/obesity**

The pooled effect size of socio-economic status and obesity/overweight is depicted in the forest plot (Figure 2). In meta-analysis, 27 studies were included. Overall, 28,814 subjects were retrieved in meta-analysis to estimate pooled effect size, and stratified as high SES/income groups and low SES/income groups. Accordingly, 9327 subjects were from high SES/income groups and 19487 subjects were from low SES/income groups. Of these high SES/income groups, 17.65% were either overweight/obese. Among 28 included articles in a meta-analysis, five studies [20,21,32-34] did not show significant association while the rest 22 studies [12-14,16,17,19,22-27,32,35-43] showed a positive association between high SES/income and obesity/overweight. The pooled effect size revealed that the likelihood of being overweight/obese is 2.35 times higher (AOR = 1.89, 95% CI: 1.75, 2.04) among high SES or high income groups compared to the low SES or income groups, heterogeneity test: Tau = 0.25, I² = 84%, df = 26, p ≤ 0.001. The chi-square test (Chi² = 160.90, df = 26) indicated that there is significant (P < 0.001) variation in set of studies. The test for overall effect (Z = 7.67) showed statistically significance at conventional levels (P ≤ 0.001).

The forest plot for the separate population group analysis (children, adolescents and adults) is depicted in Figures 3. The pooled odds ratio for separate population groups indicated the risk of overweight/obesity was

\[
\text{Magnitude of overweight obesity} = \frac{\text{Number of overweight/obese adolescents and adults}}{\text{Total number of participants included this study}} \times 100
\]

2.90 times higher (AOR = 2.90, 95%CI = 1.94, 4.36), 2.36 times higher (AOR = 2.36, 95%CI = 1.52, 3.65) and 87% higher (AOR = 1.87, 95%CI = 1.46, 2.41) among children, adolescents and adults from high SES/income groups compared to low SES/income groups respectively.

**Discussion**

Overweight and/or obese during childhood and adolescence is associated with adverse health consequences throughout the life span leading to greater risk and earlier onset of chronic disorders such as type 2 diabetes, and adverse psychosocial consequences and lowers educational attainment [44,45]. Overweight and/or obesity in adults also associated with numerous comorbidities such as cardiovascular diseases, high blood cholesterol, and sleep apnea [46].

In Ethiopia, prevention and control of overweight/obesity did receive lower attention compared to undernutrition despite it is an emerging problem leading to a double burden. The low attention in combination with limited information might increase the epidemiology of overweight/obesity among children, adolescents’ adults leading to non-communicable diseases in future life. A few cross-sectional studies conducted in Ethiopia explored considerable variation in prevalence and associated risk factors of overweight/obesity among children, adolescents, and adults across different regions. A few studies conducted showed the inconsistent result of overweight/obesity and its association with socio-economic status (SES) or wealth quantiles. This might contribute to policy and intervention strategies gaps in the country. Therefore, this systematic review and meta-analysis was aimed to explore the pooled prevalence of overweight/obesity and its association with socioeconomic status among children, adolescents and adults in Ethiopia.

The result of a pooled analysis of this study revealed that the prevalence of overweight/obesity was 13.04% in Ethiopia. This finding is lower than the result of the pooled prevalence of overweight/obesity (15.9%) from the Demographic Health Survey (DHS) analysis of 32 Sub-Saharan African countries [47]. On the other hand,
it is comparable with another meta-analysis result conducted in China where the prevalence of overweight/obesity among children and adolescents was 13.1% by the year 2010 in China [48]. Another study from United States National Nutrition and Health Examination survey 2015-2016 indicated a higher prevalence of overweight (16.6%) and obesity (18.5%) among children adults compared to the current study.

The subgroup analysis revealed that the prevalence of pooled overweight/obesity among children, adolescents and adults was 12.59%, 11.39% and 17.13% respectively. The combined child prevalence of overweight/obesity in this study is consistent with individual studies conducted in different parts of Ethiopia [12,18,39,40]. The pooled prevalence of overweight/obesity of children in this study higher than 6.8% reported from 26 countries of Sub-Saharan Demographic and Health Surveys (DHSs) [49]. The finding in this study is also lower than the result from another 10-year systematic review and meta-regression result from Europe where 17.9% of 2-7 years-old children were either overweight or obese [50].

Prevalence of pooled overweight/obesity (11.39%) among adolescents in this study is higher than individual studies in Jimma [34] and Addis Ababa [21,32,35], but lower than other studies from Addis Ababa [14,20], Bahir dar [26], Hawassa [25], Diredawa [13], and similar with another study conducted in Addis Ababa [23]. Regarding with adult overweight/obesity, the pooled result in this study (14.69%) is lower than individual study from Hawassa (28.2%) [24], and Dessie (28.5%) [16], higher than finding from Arba Minch area of Ethiopia (10.8%) [41], but in line with another study from Hawassa city (15.2%) [19]. This variation in prevalence among different studies across different regions might be explained by differences in dietary habits, lifestyle factors; and climate and agro-ecology in individual studies while the combined prevalence is average of indicated studies.

In this study, the pooled effect size or odds ratio revealed that the study subjects (children, adolescents, and adults) from high socio-economic status were 1.89 times more likely to be either overweight/obese compared to the middle to low socioeconomic status households. This finding is in line with study evidence from further analysis of EDHS (2011) such that Ethiopian women from the richest households 1.8 times more likely to be overweight/obese compared to their counterparts [38]. The finding also in line with another the result from systematic review and meta-analysis conducted in Ethiopia where children and women from high-income families were 3.16 times more likely to be overweight/obese children with middle and low-income families [51]. On the contrary, the finding of the present study in disagreement with the study report.
of further analysis of the Ethiopian demographic and health survey (EDHS) 2016 where the richest quintiles have no association with childhood overweight/obesity in Ethiopia [52]. The result of increased overweight/obesity with high socio-economic status is also in line with other studies [53,54]. Another systematic review conducted in developing countries documented similar findings where obesity is a problem of the rich in low-income countries for both men and women, while there is a mixed picture in middle-income countries [55]. On the contrary, a survey of household data from 103 countries by Templin, et al. (2019), documented that overweight prevalence increased substantially among the poorest and stayed mostly unchanged among the wealthiest [56]. Similarly, another meta-analysis by Kim and von dem Knesebeck (2018), revealed that lower-income is associated with subsequent obesity compared to higher-income [57].

This positive correlation might be, even though the overweight/obesity is a complex, multifactorial condition affected by genetic and non-genetic factors [58,59], and high socio-economic status could influence energy consumption and expenditure [60]. The imbalance increment of energy intake more than energy expenditure is considered the fundamental cause of obesity and overweight [61]. Besides, the wealthiest

---

**Figure 3:** Forest plot for the pooled odds ratio of the association between socio-economic status and overweight/obesity in Ethiopia, 2020: a: Children; b: Adolescents; c: Adults.
households would be able to afford and demand surplus foods and might be less likely to engage manual intensive work leading to less energy expenditure. On the contrary, low-income households might experience food scarcity and moderate to low food intake. Moreover, peoples from low to medium SES tend to be engaged in labor work that requires higher energy expenditure concomitantly losing body fat storage [62]. The negative correlation of low SES with overweight/obesity might be explained by that low/middle-income households probably less likely to afford expensive, nutritious, nutrient-dense, and low-calorie food but focusing in high calorie, less nutritious and cheap priced food. This truth was documented by scholars such that low-calorie food will likely be expensive for the poor leading to the consumption of a more energy-dense diet [63,64].

It is well documented that obesity is a risk factor for non-communicable diseases (NCD). At the same time, decreases quality life increases health care costs and absenteeism. Costs become unmanageable by health budget in poor countries and aligned health initiatives (more toward communicating diseases [65]. Since Ethiopia is one of the low-income countries, the current finding implies Ethiopia would be fall under the triple burden of malnutrition (micronutrient deficiency, undernutrition and over nutrition) leading to further non-communicable disease initiatives.

Conclusions

The current meta-analysis result revealed that the pooled prevalence of overweight/obesity among children, adolescents, and adults is considerably high. This indicates that overweight and or obesity is becoming an emerging nutrition-related problem. High socioeconomic status is significantly positively associated with childhood, adolescents, and adults in Ethiopia.

Recommendations

Since overweight/obesity is significantly high among children, adolescents and adults, the government of Ethiopia, health care providers, non-governmental organizations and private institutions working on childhood, adolescents and adult health should give emphasize on prevention and control of overweight and or obesity. Intensive nutrition education and counseling should be provided for households of high socioeconomic status to focus on less energy-dense or high nutrient-dense foods and engage in physical activities. Policies that focus on prevention and control of overweight/obesity with special emphasis of wealthy households should be designed and implemented in Ethiopia.

Strengths and Limitations of the Study

The main strength of this systematic review and meta-analysis is that studies from different regions of Ethiopia generated the aggregate status of overweight and obesity. The study utilized articles from reputable multiple databases. The study also generated clear information on wealth status and overweight/obesity by narrowing the confusion.

Limitation of the Study

The study focused only on published articles. Other grey literature possibly missed from the study. There might be many unpublished studies in different higher institutions of Ethiopia though it could be accessed. All the steps were conducted by one reviewer only.
